CHESS-SSIL

Chess as a Strategic Structural Intelligence Laboratory

From Competitive UIRTU-Relay to Autonomous Strategy Evolution and Collective Learning

RESEARCH OVERVIEW

Chess-SSIL is an open, falsifiable research laboratory for studying how game-state localization, per-node intelligence, competitive strategy generation, independent evaluation, and structural relay can support progressively more capable autonomous strategy systems. Chess provides a bounded reference environment; simpler games provide accessible replication paths.

CORE RESEARCH LOGIC

Game / Task State	Localization + Per-Node	Strategy Generation	Competitive Evaluation
↓ Evidence, residuals, and structural feedback ↓			
Counter-Evidence	Structural Growth / Rollback	Collective Research Relay	Validated Coverage Growth

NEW RESEARCH FRONTIER: SGP + RGC

Strategy-Generability Partition (SGP) separates reliably generable tasks from residual tasks requiring additional evidence, modeling, or oversight. Residual-to-Generable Conversion (RGC) studies how decomposition, evaluators, simulation, and portable intelligence units may move verified tasks into the generable domain. Autonomous Strategy Coverage (ASC) is proposed as a task-distribution-dependent measure of this expansion.

REPOSITORY CONTENTS

Six research papers: CSSIL-001–006: canonical game laboratory; localization; competitive relay; residual growth; collective learning; SGP/RGC.

Three technical specifications: Game-state localization and UIRTU contracts; strategy evaluation; structural-growth evidence records.

Research and figures: Open questions, testable hypotheses, validation roadmap, and five architecture figure topics.

VALIDATION PRINCIPLE

Begin with small games and controlled baselines; record failures and counter-evidence; distinguish strategy learning from autonomous structural evolution; require independent replication before claiming transfer to open-world problems. Strategy automation does not itself confer action authority.
